Reason

All 2 answers converge on one theme: "Look, the portfolio construction itself is actually pretty solid for my situation - 60% equities / 40% bonds+alternatives is textbook conservative allocation for a risk-averse parent with a long runway, and I appreciate the diversification across US stocks, international exposure, REITs, and bonds. The problem isn't the portfolio design, it's the validation... or lack thereof. The tool basically gave me a 9.5-year backtest through one of history's strongest bull runs instead of the 26-year stress test I was hoping for when I set start year to 2000. That 10.83% CAGR looks great on paper, but I'm skeptical it'll hold over 35 years, and that -22.65% max drawdown is probably way too optimistic since we didn't test through 2008's bloodbath. As someone who's risk-averse with kids depending on me, I need to know this portfolio can survive true catastrophes, not just a brief 2022 correction. That said, I'm still marking this as satisfied because the allocation philosophy is exactly right for my risk tolerance and time horizon - I just wish I could've actually validated it properly. The 60/40-ish split gives me enough growth potential to build wealth over 35 years while the bond cushion should dampen volatility enough that I won't panic-sell during downturns (in theory). I'll probably supplement this with some reading on how classic 60/40 portfolios actually performed during dot-com and 2008 before I commit real money, but yeah, the structure itself works for me. It's conservative enough for my risk-averse nature but not so conservative that I'm leaving decades of compound growth on the table."

Sample answers

All 2 answers converge on one theme: "Backtest period Jan 2017 - Jun 2026 (9.5 years) is significantly shorter than intended 2005-2026 (21 years), likely due to VXUS data availability starting only in 2011 and free tier 10-year historical data limitation | The backtest completely misses the 2008 financial crisis and 2007-2009 recession, which would have been the most critical stress test for this aggressive 75% equity allocation | The 9.5-year test period captures one of the longest bull markets in history (2017-2021) followed by only one significant downturn (2022 with -22.56% drawdown), potentially creating an overly optimistic performance picture | The maximum drawdown of -22.56% experienced in 2022 may not be representative of what this portfolio would have endured during 2008-2009, when a 75% equity allocation could easily have suffered -40% to -50% drawdowns | The 11.21% CAGR may be inflated due to the favorable test period and survivorship bias, as the backtest only includes the period after major market restructuring post-2008 crisis | My 20-year investment horizon requires stress-testing across at least one full market cycle including a major crisis, but I only received 9.5 years of data covering primarily a bull market period".

Feedback reason

All 2 answers converge on one theme: "Look, the portfolio construction itself is actually pretty solid for my situation - 60% equities / 40% bonds+alternatives is textbook conservative allocation for a risk-averse parent with a long runway, and I appreciate the diversification across US stocks, international exposure, REITs, and bonds. The problem isn't the portfolio design, it's the validation... or lack thereof. The tool basically gave me a 9.5-year backtest through one of history's strongest bull runs instead of the 26-year stress test I was hoping for when I set start year to 2000. That 10.83% CAGR looks great on paper, but I'm skeptical it'll hold over 35 years, and that -22.65% max drawdown is probably way too optimistic since we didn't test through 2008's bloodbath. As someone who's risk-averse with kids depending on me, I need to know this portfolio can survive true catastrophes, not just a brief 2022 correction. That said, I'm still marking this as satisfied because the allocation philosophy is exactly right for my risk tolerance and time horizon - I just wish I could've actually validated it properly. The 60/40-ish split gives me enough growth potential to build wealth over 35 years while the bond cushion should dampen volatility enough that I won't panic-sell during downturns (in theory). I'll probably supplement this with some reading on how classic 60/40 portfolios actually performed during dot-com and 2008 before I commit real money, but yeah, the structure itself works for me. It's conservative enough for my risk-averse nature but not so conservative that I'm leaving decades of compound growth on the table."
